(57) **ABSTRACT**

An electronic messaging device adapted to receive electronic messages from a sender. The electronic messaging device has a controller, a transmitter and receiver unit connected to the controller, a user interface connected to the controller, and a body detection device connected to the controller. After receipt of a notification message from the sender, the transmitter sends an acknowledgement message to the sender when the body detection device detects the presence of a recipient of the notification message.

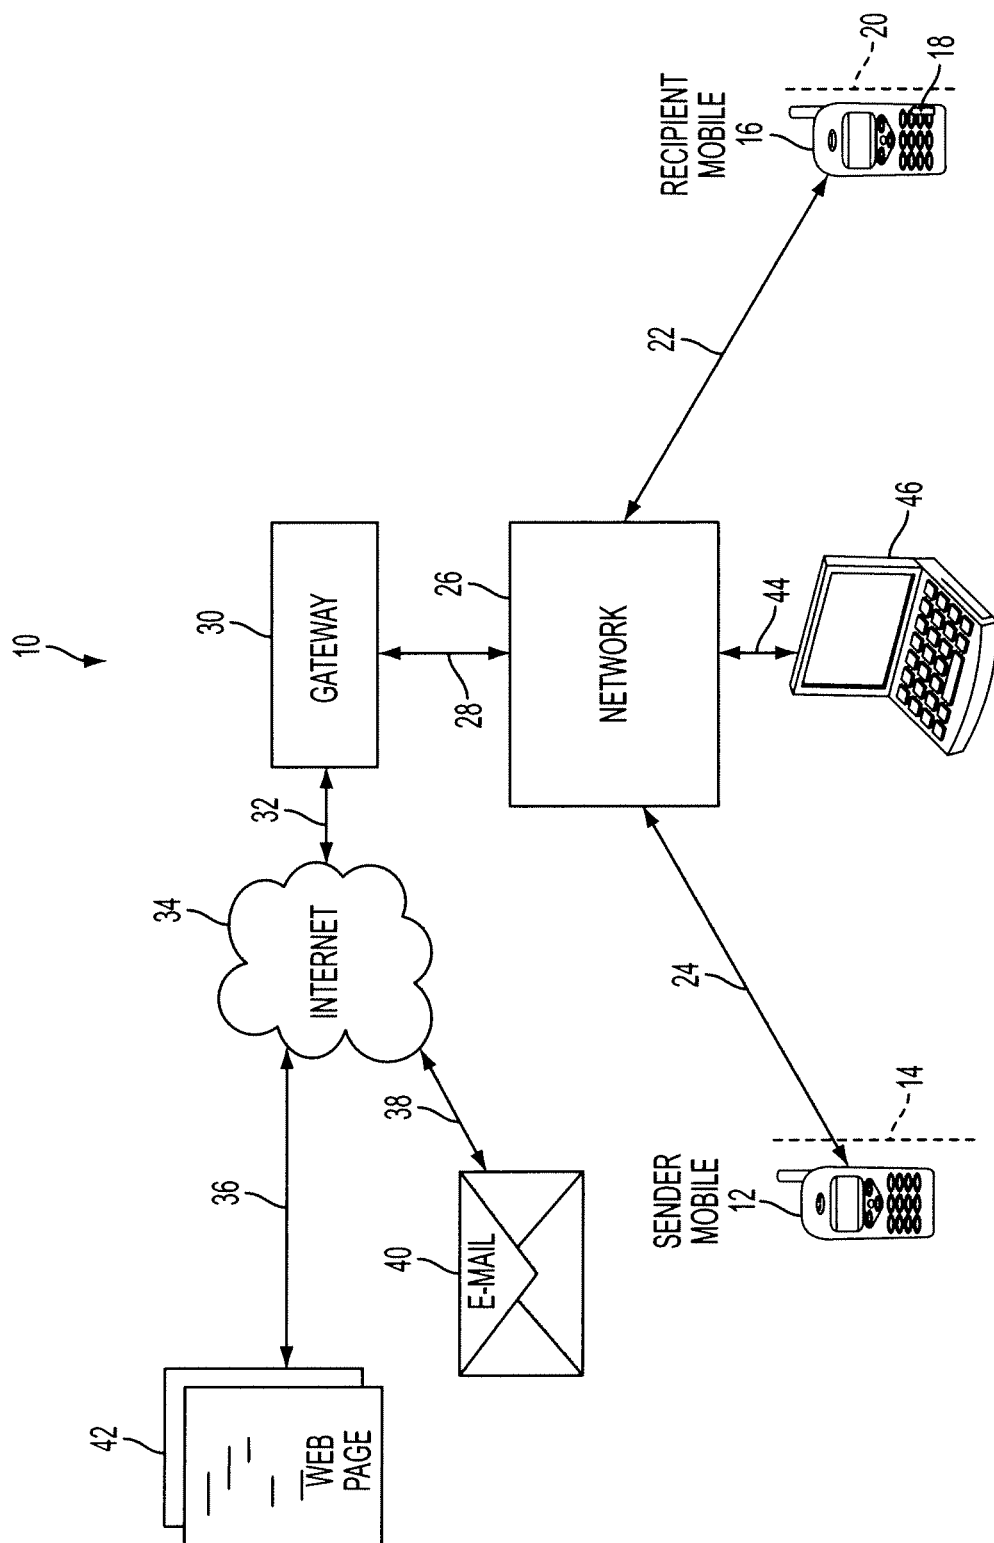

FIG. 1

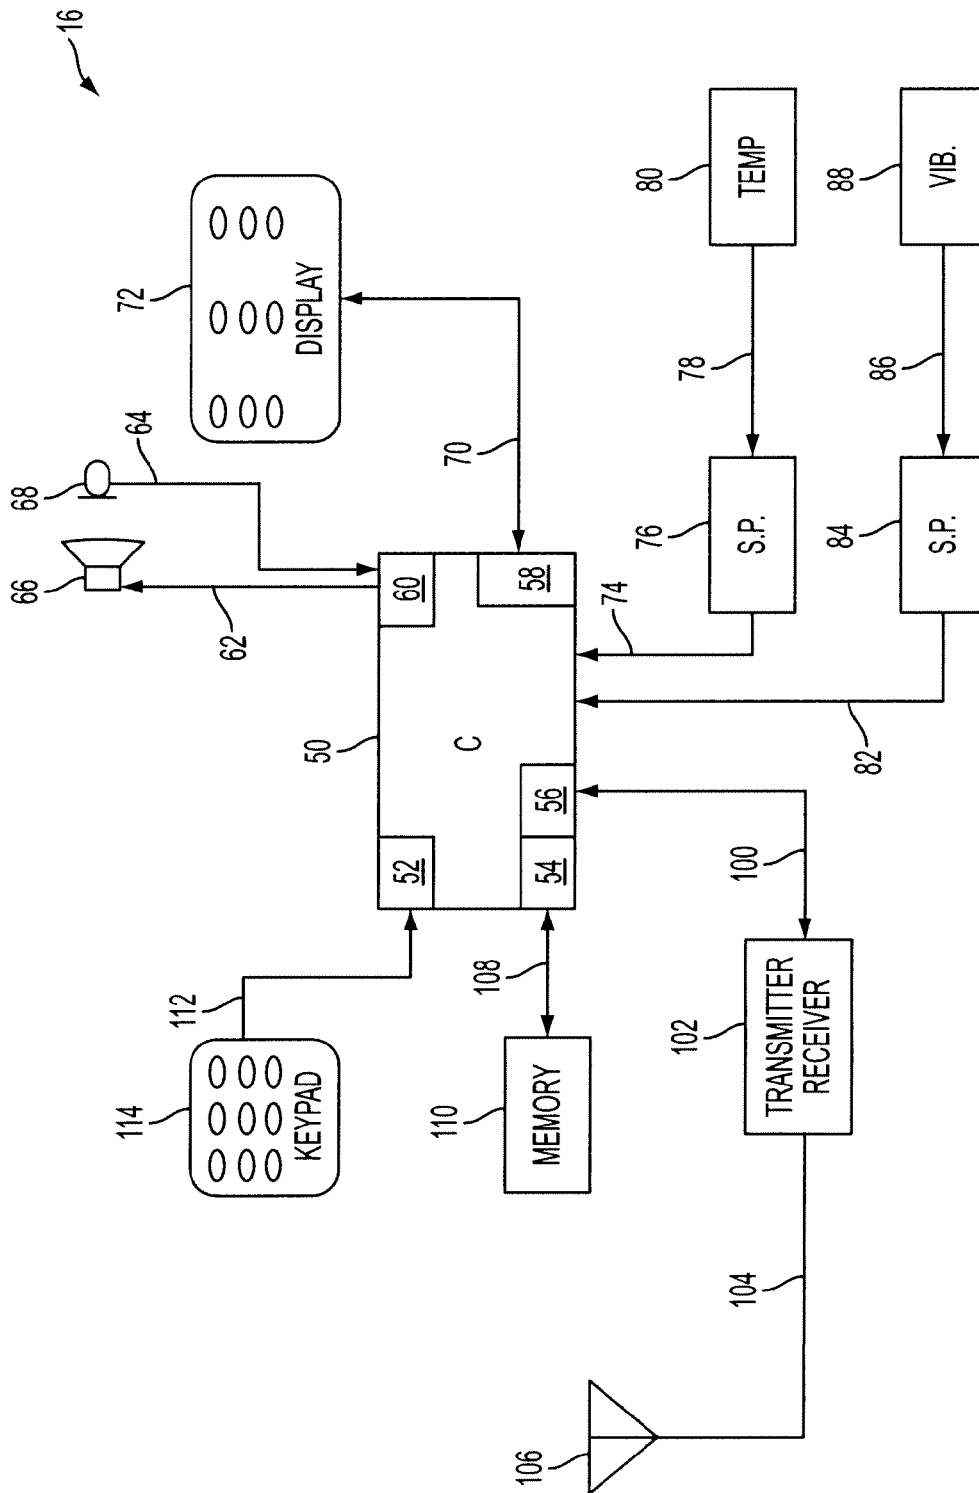

FIG. 2

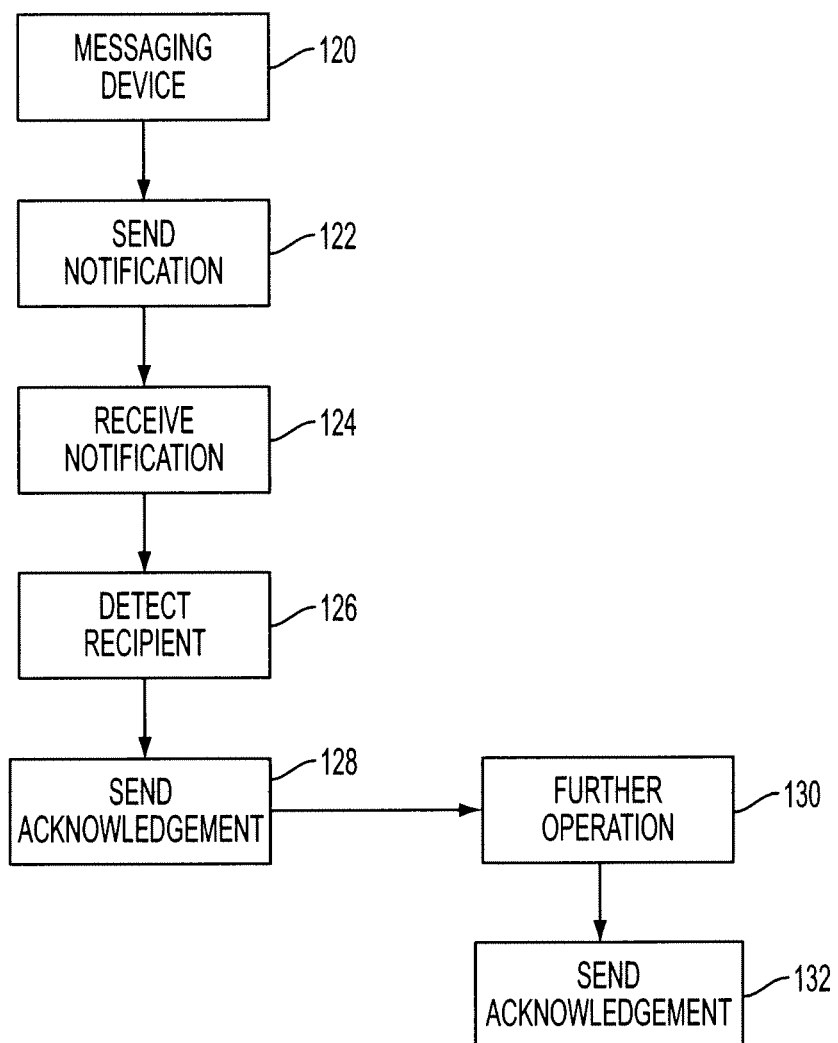

FIG. 3

1

METHOD FOR AUTOMATED ACKNOWLEDGEMENT OF ELECTRONIC MESSAGE

This application claims the benefit of U.S. Provisional Patent Application Ser. No. 61/072,343 filed Apr. 10, 2008 which is incorporated by reference herein in its entirety.

BACKGROUND

The disclosed embodiments relate to automated acknowledgement of electronic message receipt and, more particularly, to automated acknowledgement of electronic message receipt by confirmation that that messaging device is being carried by recipient.

BRIEF DESCRIPTION OF RELATED DEVELOPMENTS

Electronic messaging devices, such as cell phones or pagers, are utilized to notify a user of multiple types of messages. An example of a messaging device application involves notifying medical personnel of conditions such as critical laboratory values. In some cases, the recipient may find it advantageous to deny such notification or to delay acknowledgement, for example, to reduce potential liability. Thus, there is a desire for automated acknowledgement of electronic message receipt.

SUMMARY

In accordance with one exemplary embodiment, an electronic messaging device adapted to receive electronic messages from a sender is provided. The electronic messaging device has a controller, a transmitter and receiver unit connected to the controller, a user interface connected to the controller, and a body detection device connected to the controller. After receipt of a notification message from the sender, the transmitter sends an acknowledgement message to the sender when the body detection device detects the presence of a recipient of the notification message.

In accordance with another exemplary embodiment, an electronic messaging device adapted to receive electronic messages from a sender is provided. The electronic messaging device has a controller, a transmitter and receiver unit connected to the controller, a user interface connected to the controller, and a detection device connected to the controller, the detection device adapted to detect that the electronic messaging device is being carried by a user. After receipt of a notification message from a sender, the transmitter sends an acknowledgement message to the sender when the detection device detects that the electronic messaging device is being carried by the user.

In accordance with an exemplary method, a method for automated acknowledgement of electronic message receipt is provided having steps of providing an electronic messaging device having a transmitter and receiver unit and a body detection device, sending a notification message to the receiver from a sender, receiving the notification message, and sending an acknowledgement message from the transmitter to the sender when the body detection device detects the presence of a recipient of the notification message.

BRIEF DESCRIPTION OF THE DRAWINGS

The foregoing aspects and other features of the exemplary embodiments are explained in the following description, taken in connection with the accompanying drawings, wherein:

2

FIG. 1 is a schematic diagram of an automated acknowledgement message receipt system;

FIG. 2 is a schematic diagram of an electronic messaging device; and

FIG. 3 is a flow diagram of an automated acknowledgement message receipt method.

DETAILED DESCRIPTION

Referring now to FIG. 1, there is shown a schematic diagram of an automated acknowledgement message receipt system 10. The features of the disclosed embodiments, as will be described below, are equally applicable to any desired type of messaging system and the configuration of the system 10 in the exemplary embodiment illustrated in FIG. 1 is merely representative with the features of the exemplary embodiments described below with specific reference to the figures are equally applicable to any suitable messaging system with any desired configuration.

The disclosed embodiments are for the combination of an electronic messaging device 16, together with a method of detecting that such device is actually being carried on the body 20 of an intended recipient 20. Here, a body-detection, motion, infrared or heat sensor device 18 is incorporated into an electronic messaging device 16, for the purpose of automatically acknowledging that a message was received while the device was being actively carried on the body 20 of a person. There are many urgent notifications that must be acknowledged by intended recipients, but there are circumstances in which the recipient may find it advantageous to deny having received such notification, or to delay acknowledgement; for example, in order to reduce potential liability. In such circumstances, it is often difficult to rely on the voluntary acknowledgement of messages on the messaging device.

As an example, an exemplary use for this scheme is for notification of doctors regarding critical laboratory values, but by no means is the application intended to be limited to this circumstance. The disclosed embodiments combine a portable two-way electronic messaging device 16, for example, cellular phone, or Blackberry-type pager with a method of detecting that the device is actually being carried upon the body of a person. Such methods may include devices 18 such as motion-detection devices or body heat-detection devices, either singly or in combination. When the message is received, the device 16 would automatically send a confirmation that the message is correctly received by returning the entire message, or a mathematically unique hash/ID of the message along with device ID, time-stamp, and confirmation that the device is actively being carried on the body of recipient 20. Such messaging and acknowledgement may have incorporated encryption and secure digital signature schemes.

As seen in FIG. 1, an exemplary messaging service system architecture is shown to illustrate an embodiment of the present invention. A message service center 26, such as a cellular message service node and mobile network stores message service profiles detailing the preferences and subscription details of each subscriber with respect to messages for each of the mobile units which it services. The service center 26 uses a standard protocol to communicate with any external message entities, such as a server, an e-mail gateway or other type of messaging gateway 30, a voice processing system for handling voicemail alerts, a paging system, etc. E-mail gateway 30 is connected 32 to network 34, such as the Internet and is used as a gateway for e-mail 40 or web pages 42 or otherwise. Alternately, service center 26 may interface

directly **44** with a pc **46** or other application via wireless communication or networked communication or via the internet.

The service center **26** may ascertain whether a delivery acknowledgement is desired, for example from data received, from the content of the particular message, or from stored preferences of the originator **14** of the message. For example, the preferences of the originator **14** can be encoded in the message and service center **26** could parse the message and, based on the content of the message, decide whether and how to send a delivery acknowledgement. Service center **26** has access to a network, such as a mobile network and can ascertain where a mobile subscriber **14**, **20** is located and transmit messages from the sender **14** mobile unit **12** to the recipient **20** mobile unit **16**. Alternately, the sent and received messages may be from pc to pc, pc to mobile unit or from and to any suitable messaging device.

Service center **26** can ascertain if the recipient's mobile **16** is inactive, for example powered down or outside of the coverage area or that the subscriber's mobile is incapable of receiving a message. If the subscriber is inactive, service center **26** can keep the message in queue for a set period where once the subscriber roams back to an active area, the message can be sent. Here, if the mobile unit **16** responds, the center **26** delivers the message to the mobile unit **16** and if the message transmission is successful, the status of the message will be "sent" and center **26** will not attempt to send the message again.

Mobile unit **16** comprises an electronic messaging device adapted to receive electronic messages from sender **14**. Mobile unit **16** has a body detection device **18** that is adapted to detect that the electronic messaging device **16** is being carried by the recipient or user **20**. After receipt of a notification message from the sender **14**, the transmitter sends an acknowledgement message to the sender **14** when the body detection device **18** detects the presence of a recipient **20** of the notification message or where the detection device **18** detects that the electronic messaging device is being carried by the user **20**.

The body detection device **18** may comprise a temperature sensor where the temperature sensor detects a temperature of the recipient **20**. Alternately, the body detection device **18** may comprise a motion detector where the motion detector detects a movement of the recipient **20**. Alternately, the body detection device **18** may comprise both a temperature sensor and a motion detector where the body detection device **18** detects the presence of a recipient **20** of the notification message when the temperature sensor detects a temperature of the recipient **20** and the motion detector detects a movement of the recipient **20**. Here, the body detection device **18** detects that the electronic messaging device **16** was actively being carried upon the body of the recipient **20** of the notification message.

As shown, the electronic messaging device may comprise a cellular phone **16**. In alternate embodiments, any suitable messaging device may be provided. The acknowledgement message may comprise a copy of the notification message, a unique identifier of the electronic messaging device, a time stamp and a confirmation that the body detector **18** detected the presence of the recipient **20** of the notification message.

Referring now to FIG. 2, there is shown a schematic diagram of an electronic messaging device **16**. Here, mobile unit **16** has a controller **50**, a transmitter and receiver unit **102** connected to the controller **50**, a user interface connected to the controller **50**, and a body detection device **88** connected to the controller **50**.

As shown, the messaging device **16** may comprise a cellular phone **16** and includes an antenna **106** for transmitting and receiving electromagnetic waves, a speaker **66** for producing sound, for example a voice or a ringtone, a microphone **68** for picking up sound, for example the voice of the user, a display unit **72** may be a liquid crystal display for displaying a message, a telephone number, the content of an electronic mail, a menu screen for selecting various functions offered by an application program, the present time, the condition of electromagnetic waves, operation keys **114** for offering a direct interface to the user.

Device **16** also has a transmitter/receiver unit **102** coupled **104** to antenna **106** which is a communication module for transmitting and receiving speech and data. Device **16** further has controller **50** having a communication control unit **56** coupled **100** to transmitter and receiver **102**, a voice processing unit **60** coupled **62** to speaker **66** and **64** to microphone **68**, a temperature detector **80** coupled **78** to signal processing unit which is coupled **74** to controller **50**, where temperature detector **80** comprises a use detection module for detecting the presence of the user, a motion detector **88** coupled **86** to signal processing unit **84** which is coupled **82** to controller **50** comprises a use detection module for detecting the presence of the user. Memory **110** is coupled **108** to memory interface **54** of controller **50** comprising a ROM or a RAM for storing messages, electronic mails, browsers, software programs related to various applications such as personal schedule management, classified telephone directory, personal schedule data, transmitted and received mails, and data such as of automatic answering machine.

Device **16** further has display control unit **58** interfacing **70** to display **72** for displaying various data such as dynamic image, still image, text and the like on the display unit **72**. Device **16** has operation control unit **50** comprising chiefly a CPU for controlling the communication module and for executing the application programs depending upon a direct instruction from the user through the operation keys **114** where operation keys **114** interface **112** to key interface **52** of controller **50**. The transmitter/receiver unit **102**, communication control unit **56**, voice processing unit **60**, memory **110**, keypad interface **52**, operation control unit **50** and display control unit **58** may all be coupled together through a bus or otherwise, so that the necessary data can be exchanged among them.

Referring also to FIG. 1, body detection device **18** may comprise both a sensor and a motion detector where the body detection device **18** detects the presence of a recipient **20** of the notification message when the sensor **80** detects a temperature of the recipient **20** or infrared radiation from the recipient **20** and the motion detector **88** detects a movement of the recipient **20**. Here, the body detection device **18** detects that the electronic messaging device **16** was actively being carried upon the body of the recipient **20** of the notification message. Sensor **80** may comprise an infrared temperature detector, thermocouple or other suitable temperature or radiation detector. Sensor **80** may sense the temperature or radiation of the user directly, such as by imaging through a port on the cellular device. Alternately, sensor **80** may sense the temperature of the user indirectly where sensor **80** detects the temperature of the cellular device **16**. Signal processor **76** may be used to detect transients and changes in temperature. Controller **50** may be programmed to indicate the presence of a user when either a threshold is met or when a certain transient condition is met.

Vibration sensor **88** may comprise a sensor based on MEMS (Micro-electro mechanical systems) technology, for example, the LIS244AL 2-axis accelerometer/motion detec-

5

tor from ST Microelectronics of Geneva, Switzerland, enable microchip-sized motion detectors based on the vibrations of a silicon needle in a capacitive electric field. These are the class of detectors used to trigger airbags, and incorporated into handheld video game controllers. Alternately, sensor **88** may comprise infrared motion detectors based on pyroelectric crystals that generate a charge in response to infrared radiation may also be incorporated. An example of a miniature infrared motion detector module is the Perkin Elmer PYD 1998 Digital Pyroelectric Infrared Sensor which operates on 4 to 15 volts with 45 microampere draw. In other embodiments, body detection device **18** may include one or more sensors configured for detecting rapid fluctuation of light levels, for example, due to motion. Alternately, body detection device **18** may include one or more sensors configured for detecting pressure changes on display **72**, keys **114**, or elsewhere on the surface of device **16** resulting from, for example, unrelated recipient activity, that is, recipient activity not directly intended to acknowledge the notification message. In alternate embodiments, any suitable motion detector may be provided. Signal processor **84** may be provided to monitor trends or identify and classify types of movement. Controller **50** may be programmed to indicate the presence of a user when either a state condition is met or when a certain transient condition is met.

Referring now to FIG. **3**, there is shown a flow diagram of a method for automated acknowledgement of electronic message receipt by confirming that messaging device is being carried by the recipient. The method for automated acknowledgement of electronic message receipt has a step **120** of providing an electronic messaging device having a transmitter and receiver unit and a body detection device. The body detection device detects that the electronic messaging device was actively being carried upon the body of the recipient of the notification message. The body detection device may have a temperature sensor where the temperature sensor detects a temperature of the recipient. The body detection device may include an infrared sensor that detects infrared radiation from the recipient. Alternately, the body detection device may have a motion detector where the motion detector detects a movement of the recipient. In alternate embodiments, the body detection device may have both a temperature sensor and a motion detector where the body detection device detects the presence of a recipient of the notification message when the temperature sensor detects a temperature of the recipient and where the motion detector detects a movement of the recipient. A body detection device having a combination of an infrared sensor and a motion detector may also be utilized. In alternate embodiments any suitable detection device may be used. A step **122** of sending a notification message to the receiver from a sender is then provided. A step **124** of receiving the notification message is then provided. A step **126** of sending an acknowledgement message from the transmitter to the sender when the body detection device detects the presence of a recipient of the notification message is then provided. The acknowledgement message may have a copy of the notification message, a unique identifier of the electronic messaging device, a time stamp and a confirmation that the body detector detected the presence of the recipient of the notification message. In alternate embodiments, more or less data may be provided in the acknowledgement message. A step **130** of further operation of the electronic messaging device by the recipient is then provided. A step **132** of sending a second acknowledgement message from the transmitter to the sender when the recipient conducts a further operation of the electronic messaging device after receipt of the notification message is then provided.

6

It should be understood that the foregoing description is only illustrative of the disclosed embodiments. Various alternatives and modifications can be devised by those skilled in the art without departing from the disclosed embodiments. Accordingly, the present disclosed embodiments are intended to embrace all such alternatives, modifications and variances which fall within the scope of the exemplary embodiments.

What is claimed is:

1. A method for automated acknowledgement of electronic message receipt comprising:

providing an electronic messaging device having a transmitter and receiver unit and a body detection device, sending a notification message to the receiver from a sender, receiving the notification message, and sending an acknowledgement message from the transmitter to the sender when the body detection device detects the presence of a recipient of the notification message without voluntary acknowledgement by the recipient.

2. The method for automated acknowledgement of electronic message receipt of claim **1** further comprising the step of sending a second acknowledgement message from the transmitter to the sender when the recipient conducts a further operation of the electronic messaging device after receipt of the notification message.

3. The method for automated acknowledgement of electronic message receipt of claim **1**, wherein the body detection device detects that the electronic messaging device was actively being carried upon the body of the recipient of the notification message.

4. The method for automated acknowledgement of electronic message receipt of claim **1**, wherein the body detection device comprises a temperature sensor, and wherein the temperature sensor detects a temperature of the recipient.

5. The method for automated acknowledgement of electronic message receipt of claim **1**, wherein the body detection device comprises a motion detector, and wherein the motion detector detects a movement of the recipient.

6. The method for automated acknowledgement of electronic message receipt of claim **1**, wherein the acknowledgement message comprises a copy of the notification message, a unique identifier of the electronic messaging device, a time stamp and a confirmation that the body detector detected the presence of the recipient of the notification message.

7. The method for automated acknowledgement of electronic message receipt of claim **1**, wherein the body detection device comprises a temperature sensor and a motion detector, and wherein the body detection device detects the presence of a recipient of the notification message when the temperature sensor detects a temperature of the recipient and the motion detector detects a movement of the recipient.

8. An electronic messaging device adapted to receive electronic messages from a sender, the electronic messaging device comprising:

a controller, a transmitter and receiver unit connected to the controller, a user interface connected to the controller, and a body detection device connected to the controller,

wherein, after receipt of a notification message from the sender, the transmitter sends an acknowledgement message to the sender when the body detection device detects the presence of a recipient of the notification message without voluntary acknowledgement by the recipient.

7

9. The electronic messaging device of claim 8, wherein the body detection device comprises a temperature sensor, and wherein the temperature sensor detects a temperature of the recipient.

10. The electronic messaging device of claim 8, wherein the body detection device comprises a motion detector, and wherein the motion detector detects a movement of the recipient.

11. The electronic messaging device of claim 8, wherein the body detection device detects that the electronic messaging device was actively being carried upon the body of the recipient of the notification message.

12. The electronic messaging device of claim 8, wherein the electronic messaging device comprises a cellular phone.

13. The electronic messaging device of claim 8, wherein the acknowledgement message comprises a copy of the notification message, a unique identifier of the electronic messaging device, a time stamp and a confirmation that the body detector detected the presence of the recipient of the notification message.

14. The electronic messaging device of claim 8, wherein the body detection device comprises a temperature sensor and a motion detector, and wherein the body detection device detects the presence of a recipient of the notification message when the temperature sensor detects a temperature of the recipient and the motion detector detects a movement of the recipient.

15. An electronic messaging device adapted to receive electronic messages from a sender, the electronic messaging device comprising:

a controller,

8

a transmitter and receiver unit connected to the controller, a user interface connected to the controller, and a detection device connected to the controller, the detection device adapted to detect that the electronic messaging device is being carried by a user,

wherein, after receipt of a notification message from a sender, the transmitter sends an acknowledgement message to the sender when the detection device detects that the electronic messaging device is being carried by the user without voluntary acknowledgement by the user.

16. The electronic messaging device of claim 15, wherein the detection device comprises a temperature sensor, and wherein the temperature sensor detects a temperature of the user.

17. The electronic messaging device of claim 15, wherein the detection device comprises a motion detector, and wherein the motion detector detects a movement of the user.

18. The electronic messaging device of claim 15, wherein the electronic messaging device comprises a cellular phone.

19. The electronic messaging device of claim 15, wherein the acknowledgement message comprises a copy of the notification message, a unique identifier of the electronic messaging device, a time stamp and a confirmation that the detection device detected the presence of the user.

20. The electronic messaging device of claim 15, wherein the detection device comprises a temperature sensor and a motion detector, and wherein the detection device detects the presence of the user when the temperature sensor detects a temperature of the user and the motion detector detects a movement of the user.

* * * * *
